

# HelloGrowthCRM Technical Audit

## Front-End Performance & SEO Screening Report

| CANDIDATE NAME | TARGET WEBSITE     | AUDIT DATE     | AUDIT SCOPE               |
|----------------|--------------------|----------------|---------------------------|
| Jeevan M       | hellogrowthcrm.com | August 8, 2026 | Mobile PageSpeed & Source |

### TASK 1 Mobile PageSpeed Score & Baseline Metrics

Figure 1: PageSpeed Insights Report for https://hellogrowthcrm.com (Mobile viewport). Audit date: 08 Aug 2026.

| Metric Name                     | Field Data (Real Users) | Lab Data (Lighthouse) | Status / Benchmark            |
|---------------------------------|-------------------------|-----------------------|-------------------------------|
| Performance Score               | 85 / 100                | 85 / 100              | Needs Improvement (85 circle) |
| Largest Contentful Paint (LCP)  | 5.4 s                   | 3.7 s                 | Poor (> 2.5s) — FAILED        |
| Interaction to Next Paint (INP) | 241 ms                  | 160 ms (TBT)          | Needs Improvement (> 200ms)   |
| Cumulative Layout Shift (CLS)   | 0.00                    | 0.006                 | Good (< 0.1) — PASSED         |
| First Contentful Paint (FCP)    | 4.4 s                   | 2.0 s                 | Poor (> 1.8s)                 |
| Time to First Byte (TTFB)       | 3.3 s                   | —                     | Poor (> 0.8s)                 |

## TASK 2 Top 3 Performance Fixes (Prioritized by Impact)

The following top 3 fixes directly address the root causes identified in the PageSpeed report and page source code, focusing on LCP and INP bottlenecks.

### Fix #1: Optimize TTFB & Edge HTML Caching to Unblock LCP

Target Metric: LCP & FCP

**Why:** Field metrics reveal a high Time to First Byte (TTFB = 3.3s) and First Contentful Paint (FCP = 4.4s). Because LCP elements cannot begin rendering until the initial document HTML is fully received, server response latency directly limits mobile LCP to 5.4s.

**Evidence:** PageSpeed Mobile Field Data (TTFB: 3.3s, FCP: 4.4s, LCP: 5.4s) establishing initial HTML network wait time as the dominant delay factor.

**Action Plan:** Implement Edge SSR / CDN Stale-While-Revalidate caching (via Vercel Edge / Cloudflare) for marketing page HTML and optimize database queries.

**Estimated Improvement:** LCP -1.5s to -2.5s | FCP -1.5s to -2.5s

### Fix #2: Defer Non-Critical Next.js JavaScript & Hydration Bundles

Target Metric: INP (Interaction to Next Paint)

**Why:** PageSpeed flags 85 KiB of unused JavaScript and 4 long main-thread execution tasks. Page source inspection shows 15+ static Next.js JS chunks (`/_next/static/chunks/...`) loaded in `<head>`. Main-thread blockages during script evaluation create input delay when users tap buttons or links.

**Evidence:** PageSpeed Audit "Reduce unused JavaScript" (85 KiB savings), 4 Long Tasks, and 15+ chunk script tags in the HTML `<head>`.

**Action Plan:** Code-split below-the-fold components using Next.js `dynamic()` imports with `{ ssr: false }` and load interactive scripts after main thread idle state via `requestIdleCallback`.

**Estimated Improvement:** INP -40ms to -80ms (Lowering INP from 241ms into the <200ms "Good" green zone).

### Fix #3: Remove Duplicate Preloads & Refine Mobile Hero Image Sizing

Target Metric: LCP (Largest Contentful Paint)

**Why:** Page source analysis reveals duplicate `<link rel="preload" as="image">` tags in the HTML `<head>`. Serving high-resolution desktop WebP image variants alongside mobile variants without narrow media query constraints leads to redundant bandwidth usage on mobile cellular networks.

**Evidence:** HTML page source lines featuring duplicate `<link as="image" fetchpriority="high" imagesrcset="/og/dashboard-hero-640.webp 640w, /og/dashboard-hero.webp 900w" rel="preload"/>` tags.

**Action Plan:** Deduplicate preload tags in HTML generation and attach explicit media queries (e.g. `media="(max-width: 640px)"`) to ensure mobile viewports fetch strictly sized assets.

**Estimated Improvement:** LCP -0.4s to -0.8s

## TASK 3 SEO Problem Identified from Page Source

### Issue: Self-Referential Canonical URL & Open Graph Target Mismatch on Root Homepage

Exact HTML Code Evidence (Extracted directly from View Page Source of <https://hellogrowthcrm.com/>):

```
<!-- Requested Root URL: https://hellogrowthcrm.com/ --> <link rel="canonical"
href="https://hellogrowthcrm.com/in" /> <meta property="og:url"
content="https://hellogrowthcrm.com/in" />
```

#### Why it hurts SEO:

When search engine crawlers (such as Googlebot) access the primary root domain (<https://hellogrowthcrm.com/>), the canonical tag explicitly points to the regional subpath ([/in](https://hellogrowthcrm.com/in)). This self-referential canonical mismatch instructs search engines to treat the primary homepage as duplicate content of the regional subpath. As a result, search engines consolidate indexing signals and organic ranking authority onto [/in](https://hellogrowthcrm.com/in), causing external backlinks, domain authority, and social sharing signals aimed at [hellogrowthcrm.com](https://hellogrowthcrm.com) to suffer link equity dilution and canonical indexing conflicts.

## Audit Conclusion & Assessment

#### Overall Assessment:

HelloGrowthCRM presents a modern Next.js implementation featuring clean initial optimizations (preloaded critical CSS, localized hreflang tags, single H1 element, and a 100/100 lab SEO score). Rectifying the canonical URL mismatch on the root homepage and implementing edge caching for TTFB alongside hydration bundle splitting for INP will bring real-user Core Web Vitals into full compliance.
